

# CS286 Solving Big Data Problems – Exam #2 Study Guide

By: Zayd Hammoudeh

## Lecture #14 – Introduction to Data Science

### Features

<p><b>Model = SampleData + Algorithm(s)</b></p> <p><b>Feature</b> – Individual, measurable property of an observation. In supervised learning, it is used for predicting the target.</p> <p><b>Additional Names:</b></p> <ul style="list-style-type: none"> <li>Predictor</li> <li>Attribute</li> <li>Variable</li> </ul> <p><b>Vectorizing Data</b> – Given an observation, assign features to dimensions.</p>	<p><b>Attribute Types</b></p> <ul style="list-style-type: none"> <li><b>Continuous</b> (Numeric) – Data across a continuum.</li> <li><b>Binary</b> – Two possible values.</li> <li><b>Categorical</b> – Finite set of possible values.</li> <li><b>Text</b> – Vocabulary or n-gram. <ul style="list-style-type: none"> <li><b>Bi-gram</b> – 2 consecutive words.</li> </ul> </li> </ul>	<p><b>Qualities of Good Features/Feature Sets</b></p> <ul style="list-style-type: none"> <li><b>Correlation</b> with the target (i.e. class value)</li> <li>Features are <b>independent</b></li> <li><b>Number of Features in Minimized</b></li> <li><b>Number of features is much less than the number of data points.</b></li> <li><b>Features do not leak the target</b> meaning they do not provide information that would not be available under normal circumstances.</li> </ul>
---	---	--

<p><b>Set Dimensionality {m, n}</b></p> <ul style="list-style-type: none"> <li><b>m</b> – Number of observations</li> <li><b>n</b> – Number of Features</li> </ul> <p>Ideally: <math>m \gg n</math></p>	<p><b>Principal Component Analysis Procedure – Dimensionality Reduction</b></p> <p><b>Procedure</b></p> <ol style="list-style-type: none"> <li>Calculate covariance matrix of the original input matrix.</li> <li>Perform eigenvalue decomposition of the covariance matrix.</li> <li>Look for orthogonal dimensions with the greatest variance (principal)</li> <li>Project input matrix into those dimensions.</li> </ol> <p>Relative covariance preserved across projection.</p>	<p><math>\lambda</math> – Representation of the total variance of the principal components.</p> $\lambda = [4.2, 0.24, 0.08, 0.02] = \frac{4.2 + 0.24}{4.2 + 0.24 + 0.08 + 0.02} = 98\%$ <p>Number of principal components and eigenvectors equivalent to the number of dimensions in the original input matrix.</p> <p>Since the data is mapped to new dimensions, not easy to map principal components to the original data.</p>
---	---	--

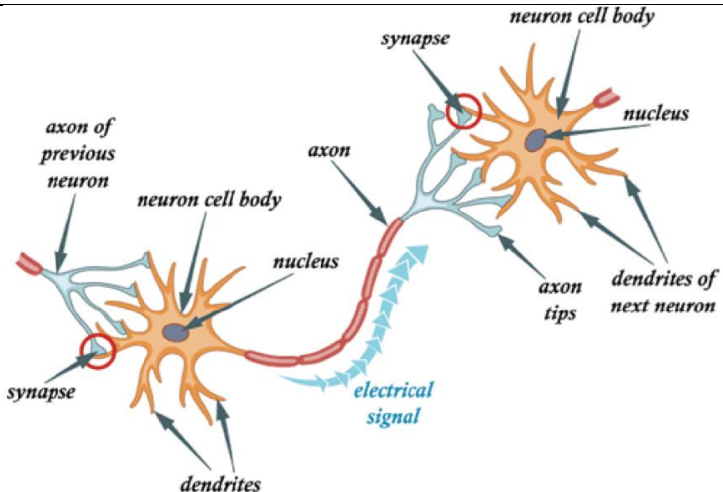

<p><b>Feature Scale</b></p>		<p><b>Target Leaks</b> – Sample data has “extra” information/features not found outside the sample. May cause the model to be unrealistically good.</p> <p><b>Bias</b></p> <ul style="list-style-type: none"> <li><b>Sampling Bias</b> – Non-representative sample</li> <li><b>Observer Bias</b> – Corrupted/invalid measurement of features</li> <li><b>Funding Bias</b> – “Fudging”/manipulating of the data.</li> </ul> <p><b>Simpson’s Paradox</b> – Trend that appears in different groups disappears (or changes) groups are combined. Example: The average of averages does not equal the average all points.</p>
<p><b>Potential Issues</b></p> <ul style="list-style-type: none"> <li><b>Relative Magnitude</b> – Some features may have different magnitude than others causing those features to dominate.</li> <li><b>Absolute Magnitude</b> – When features are too large or too small, data may be lost to overflow or underflow respectively.</li> </ul>	<p><b>Potential Solutions</b></p> <ul style="list-style-type: none"> <li><b>Standardization</b> – Transform data to measure how many standard deviations it is from the mean. <math display="block">x' = \frac{x - \bar{x}}{\sigma_x}</math> </li> <li><b>Normalization</b> – Transform data such that the range is between 0 and 1. <math display="block">x' = \frac{x - x_{min}}{x_{max} - x_{min}}</math> </li> </ul>	

### Algorithms and Evaluation

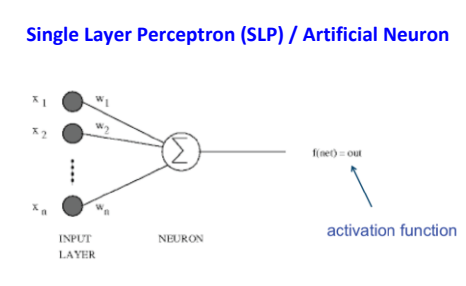

<p><b>Applications of Clustering</b></p> <ul style="list-style-type: none"> <li>Image Segmentation</li> <li>Dendrogram (including Phylogenetic Dendrogram)</li> <li>Market Segmentation</li> </ul>	<p><b>K-Means Clustering Algorithm</b></p> <ol style="list-style-type: none"> <li>Initialize the K centroid</li> <li>Assign points to the nearest centroid.</li> <li>Update the centroids.</li> <li>Check Stop Conditions</li> </ol>	<p><b>Methods for Selecting the Initial Clusters</b></p> <ol style="list-style-type: none"> <li>Random</li> <li>El Agha et. al. Method</li> <li>All at the same point (e.g. origin)</li> </ol> <p><b>Stop Condition Options</b></p> <ol style="list-style-type: none"> <li>Min change of median from last iteration.</li> <li>Sufficiently small intra-cluster distance</li> <li>Sufficiently large intercluster distance</li> </ol>	<p><b>Intracluster Distance</b> – Distance between points within the same cluster. Measures the cluster’s similarity.</p> <p><b>Intercluster Distance</b> – Distance between the centroids. Measures data separation between clusters.</p>
--	--	--	--

<p><b>Naïve Bayes</b></p> $P(C F_1, \dots, F_n) = \frac{P(C) \cdot P(F_1 C) \cdot \dots \cdot P(F_n C)}{P(F_1, \dots, F_n)}$ <ul style="list-style-type: none"> <li>Assumes all features are <b>conditionally independent</b>.</li> <li><b>C</b> – A class value</li> <li><b>F<sub>i</sub></b> – The <i>i</i><sup>th</sup> feature.</li> <li>The predicted class value is the one with the <b>highest Naïve Bayes probability</b>.</li> </ul>	<p><b>Sensitivity/True Positive Rate</b></p> $TPR = \frac{TP}{TP + FN}$ <p><b>Specificity/True Negative Rate</b></p> $TNR = \frac{TN}{TN + FP}$ <p><b>Accuracy</b></p> $Acc = \frac{TP + TN}{TP + FN + FP + TN}$	<ul style="list-style-type: none"> <li>For some domains (e.g. SPAM and cancer detection), you may use a weight function as different types of misclassification may have different costs.</li> </ul>
---	--	--

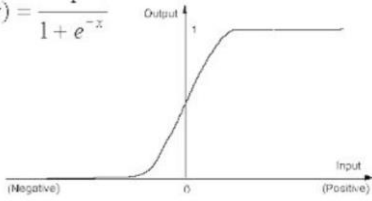

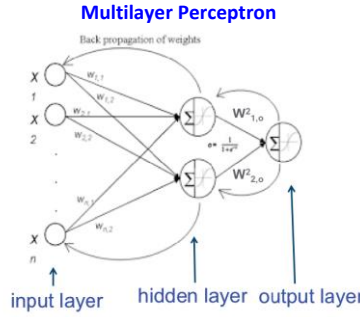

<p><b>K-Nearest Neighbors (KNN)</b></p> <p>Example Distance Metrics</p> <ul style="list-style-type: none"> <li>• Euclidean</li> <li>• Manhattan</li> <li>• Cosine</li> </ul> <p><b>Voting Related Issues:</b></p> <ul style="list-style-type: none"> <li>• May be <b>problematic if class distribution is skewed</b>.</li> <li>• Could <b>use distance as a weight</b>.</li> <li>• May want to <b>pick an odd number for k to avoid ties</b>.</li> </ul>	<p><b>Types Recommendation Filtering</b></p> <ul style="list-style-type: none"> <li>◦ Item Based</li> <li>◦ User Based</li> </ul> <p><b>Precision</b> – Proportion of <b>top-search results that are relevant</b>.</p> $Precision = \frac{TP}{TP + FP}$ <p><b>Recall</b> – Proportion of <b>relevant results that are top-scoring</b>.</p> $Recall = \frac{TP}{TP + FN}$	<p><b>Underfitting</b> – Model is too simple for the data set.</p> <p><b>Overfitting</b> – Model is overly trained to match the training set.</p> <p><b>Occam's Razor</b> – Most plausible explanation is the simplest one.</p> <p><b>Pessimistic Estimation</b> – Impose a penalty (<math>\lambda</math>) in cost function based on model.</p> <ul style="list-style-type: none"> <li>• <b>Smaller <math>\lambda</math></b> – Overfitting</li> <li>• <b>Larger <math>\lambda</math></b> – Underfitting</li> </ul>	<p><b>Sunrise Problem</b></p> <p><math>P(\text{sun will rise tomorrow}) = ?</math></p> <p>Using existing observations the probability is one but there will be a day when it does not rise.</p> <p><b>Smoothing:</b> Use probability distributions for parameter estimates for sparse data.</p> $\hat{\theta}_i = \frac{x_i + \alpha}{N + \alpha \cdot d}$ <ul style="list-style-type: none"> <li>• <b>Smaller <math>\alpha</math></b> – Overfitting</li> <li>• <b>Larger <math>\alpha</math></b> – Underfitting</li> </ul>
--	--	--	---

<p><b>Cross Validation</b></p> <ul style="list-style-type: none"> <li>• Leave <math>k</math> out.</li> <li>• Train on the <math>N - k</math> points. Use the <math>k</math> points to estimate the out of sample error.</li> <li>• Repeat this process until all points have appeared in the training set exactly once.</li> <li>• <b>Example: Leave-1-Out.</b> Generate and train <math>N</math> models. Using this approach, the error is:</li> </ul> $Error_{LeaveOneOut} = \frac{1}{N} \cdot \sum_{i=1}^N e_i$ <ul style="list-style-type: none"> <li>• <b>Cross validation can be repeated with different model parameters. Select the model with the lowest cross validation error.</b></li> </ul>	<p><b>K-Fold Cross Validation</b> – Divide the training set into <math>k</math> equally sized pieces. Example: <math>k = 10</math> means each testing set is size <math>\frac{N}{10}</math>.</p> <p><b>Downside of Leave-One-Out</b> – Computationally expensive.</p>	
--	---	--

## Lecture #15 – Introduction to Machine Learning

<p><b>Machine Learning</b> – A subfield of computer science that deals with the construction and study of systems that can learn from data rather than follow explicitly programmed instructions</p>	<p><b>Neuron</b> – A brain cell.</p> <p><b>Dendrite</b> – Appendages that stick out from a neuron.</p> <p><b>Axon</b> – Long chain that connects two neurons' dendrites. Carries the electrical signal between two cells.</p> <p><b>Synapses</b> – Small cleft or separation between two neurons.</p>	<ul style="list-style-type: none"> <li>• <b>When neuron A repeatedly participates in firing neuron B, the strength of the action from A to B increases. Cells that fire together wire together.</b> <ul style="list-style-type: none"> <li>◦ <b>If they fire separately, the weight decreases.</b></li> </ul> </li> <li>• <b>Synaptic Strength</b> – Can be modeled as a set of weights.</li> <li>• <b>Hebbian Learning</b> – Changing of the weights between the neurons in the brain.</li> </ul>	<p><b>Single Layer Perceptron (SLP) / Artificial Neuron</b></p> 
--	---	--	---

<p><b>Activation Function</b> – Defines the relation between the summed input to the perceptron and the perceptron's output.</p> <p><b>Perceptron's can be taught to recognize a binary pattern</b> (e.g. 0 or 1)</p>	<p><b>Rosenblatt Perceptron Learning Algorithm</b></p> <p><b>Step #1:</b> Initialize weights and perceptron thresholds (e.g. randomly).</p> <p><b>Step #2:</b> For each input (<math>\vec{x}</math>) and expected/desired output (<math>d</math>), do the following:</p> <ul style="list-style-type: none"> <li>◦ Calculate the net signal via: <math>\vec{x}^T \vec{w}</math></li> <li>◦ Calculate the perceptron's output: <math>y_j(t) = \text{sign}(\vec{x}^T \vec{w})</math></li> <li>◦ Compute the error (one of the set <math>\{-1, 0, 1\}</math>): <math>e_j(t) = d_j(t) - y_j(t)</math></li> <li>◦ Update the weights <math>w_i(t+1) = w_i(t) + \alpha \cdot e_j(t) \cdot x_{ij}</math></li> </ul> <p><b>Step #3:</b> If stop condition met, then terminate, else repeat step #2.</p>	<p><b>Sigmoid Activation Function</b></p> $f(x) = \frac{1}{1 + e^{-x}}$ <p><b>Benefits of the Sigmoid Function:</b></p> <ul style="list-style-type: none"> <li>• Good approximation of the step function</li> <li>• Permits a continuous output</li> <li>• Solves noise saturation for large signals.</li> <li>• Solves noise attenuation for small signals.</li> <li>• Has a simple first order derivative.</li> </ul>
---	--	---

<p><b>Sigmoid Function</b></p> $f(x) = \frac{1}{1 + e^{-x}}$ 	<p><b>Deficiency of the Perceptron</b> – Cannot solve all functions. <b>Example:</b> XOR.</p> <ul style="list-style-type: none"> <li>Discovered by <b>Minsky and Papert</b>.</li> </ul> <p><b>Perceptron Functions must be linearly separable.</b></p>	<p><b>Multilayer Perceptron</b></p> 	<p><b>Multilayer Perceptron:</b> Developed by <b>Werbos</b></p> <p><b>Two Stages:</b> Repeat until <b>convergence</b></p> <ul style="list-style-type: none"> <li><b>Forward Pass</b> – Use the inputs to <b>calculate the outputs and deltas for each neuron</b>.</li> <li><b>Reverse Pass</b> – <b>Adjust the weights by fractions (<math>\alpha</math>) of the deltas</b>. Done via <b>back propagation</b> layer to layer.</li> </ul> <p><b>Multilayer perceptrons are trained to recognize patterns.</b> <b>Example:</b> Handwriting recognition.</p> <p><b>Can compute XOR.</b></p>

machine learning

supervised

unsupervised

Lots of other algorithms that sit in the middle here somewhere

- Classification
  - KNN
  - Decision tree
- Regression
  - linear
  - logistic

- Clustering
  - K-means
  - DBSCAN
- Dimensionality reduction
  - PCA
  - SVD

<p><b>Single Layer Perceptrons can learn linearly separable functions only.</b></p> <p><b>Multilayer perceptrons can learn linearly and non-linearly separable functions.</b></p>	<p><b>Supervised learning has input-output pairs during the training phase</b> (i.e. labeled data).</p> <p><b>Unsupervised learning does not have outputs</b> (i.e. unlabeled data).</p>	<p><b>Classification Problems</b> – Have a finite set of outputs.</p> <p><b>Regression Problems</b> – Do not have a finite set of outputs.</p>
---	--	--

## Lecture #17 – Classification

<p><b>Classification</b> – A supervised machine learning algorithm. Distinguishes objects of one class from another. Emulates human decision making.</p> <p><b>Example of Classification:</b></p> <ul style="list-style-type: none"><li>• Credit card fraud detection</li><li>• Credit approval</li></ul> <p><b>Example of Regression:</b></p> <ul style="list-style-type: none"><li>• Credit card profitability.</li></ul>	<p><b>Feature Extractor</b> – Given an input object, builds/extracts the set of features.</p> <p><b>Machine Learning Algorithm</b> – Generates the classifier model.</p> <p><b>Classifier Model</b> – Given an input, predicts a class label/value.</p>	<p><b>Feature / Predictor Attribute Types</b></p> <ul style="list-style-type: none"><li>• <b>Continuous</b> – Decimal or floating point.<ul style="list-style-type: none"><li>◦ <b>Example:</b> 0.1</li></ul></li><li>• <b>Categorical</b> – Predefined, finite set of values.<ul style="list-style-type: none"><li>◦ <b>Example:</b> { true, false }</li></ul></li><li>• <b>Work-like</b> – Large set of defined values.<ul style="list-style-type: none"><li>◦ <b>Example:</b> English dictionary</li></ul></li><li>• <b>Text-Like</b> – Sequence of word-like objects.<ul style="list-style-type: none"><li>◦ <b>Example:</b> Email message subject.</li></ul></li></ul>	
<p><b>Bayes Theorem</b></p> $P(A B) = \frac{P(B) \cdot P(B A)}{P(A)}$ <ul style="list-style-type: none"><li>• Can be used to prove the Monty Hall problem.</li></ul>	<p><b>Assumptions of Naïve Bayes</b></p> <ol style="list-style-type: none"><li>1. Input data is labeled.</li><li>2. Predictors are in <i>N</i>-dimensional space.</li><li>3. Target is a set of categorical values</li><li>4. Class C is dependent on the set of input attributes.</li><li>5. All features are conditionally independent.</li></ol>	<p><b>Naive Bayes may not be Bayesian</b> since it simplifies the problem by the independence assumption.</p> <p><b>Bag of Words</b> – Transform a text input into an unordered set of words.</p>	<p><b>Calculating Conditional Probability</b></p> $P(C A) = \frac{N_{A,C} + 1}{N_C + k}$ <ul style="list-style-type: none"><li>• <i>N<sub>C</sub></i> – Number of elements of class <i>C</i></li><li>• <i>N<sub>A,C</sub></i> – Number of elements of class <i>C</i> with attribute <i>A</i></li><li>• <i>k</i> – Number of classes.</li></ul>
<p><b>Sequence of Mahout Commands</b></p> <ul style="list-style-type: none"><li>• mahout seqdirectory</li><li>• mahout seq2sparse</li><li>• mahout split</li><li>• mahout trainnb</li><li>• mahout testnb</li></ul>			

## Lecture #13a – HBase

<p><b>Relational Database</b> – A datastore that whose <b>type and structure is defined before storage</b>. Uses SQL.</p> <p><b>Deficiencies of Relational Databases</b></p> <ul style="list-style-type: none"><li>Do not scale horizontally.</li><li>Sharding is difficult to manage (join and transactions do not scale across shards)</li></ul>	<p><b>HBase</b> – A distributed database where puts and gets are accessed via a key.</p> <p><b>Table Splits</b> – Occur automatically as the table grows.</p> <p><b>Horizontal Partitioning</b> – Putting rows into different tables. HBase uses <b>key ranges/regions</b> to <b>define the horizontal partitions (shards)</b>.</p>	<p><b>Row Key</b> – Used to store and access data.</p> <p><b>Column Family</b> – Used to group and store similar data (i.e. <b>subcolumns – column qualifiers</b>). Attributes of column families include:</p> <ul style="list-style-type: none"><li>Number of versions</li><li>Time to Live (TTL)</li><li>Compression</li><li>Key in memory or preserve to disk.</li></ul> <p>Column family are separated into different files</p>	
<p><b>Pros of HBase:</b></p> <ul style="list-style-type: none"><li>Scalable to handle data volume and velocity.</li><li>Fast reads and writes by key.</li></ul> <p><b>Cons of HBase:</b></p> <ul style="list-style-type: none"><li>Does not support joins</li><li>Good schema design is needed to achieve the best performance.</li></ul>	<p>Data is stored in a key-value model.</p> <p><b>Information Required to Access a Single Cell Value in HBase</b></p> <ul style="list-style-type: none"><li>Row Key</li><li>Column Family</li><li>Column Qualifier (i.e. subcolumn name)</li><li>Timestamp/Version</li></ul>	<p><b>Version in HBase</b></p> <ul style="list-style-type: none"><li>Each put and delete adds a new version/cell.</li><li>Stores last 3 versions by default.</li><li>Version – Stored as a long which is the current time in milliseconds (if no specific version is specified)</li></ul>	<p><b>Table Physical View</b></p> <ul style="list-style-type: none"><li>Stored as a <b>sorted map</b>.</li><li>Ordered by <b>row key and column qualifier in ascending order</b>.</li><li>Ordered by version/timestamp in <b>descending order</b>.</li></ul>
<p><b>Basic Table Operations</b></p> <ul style="list-style-type: none"><li>Create table and defining of column families is done before data is imported.</li></ul> <p><b>Basic CRUD Operations</b></p> <ul style="list-style-type: none"><li>Put – Insert data into rows (both create and update)</li><li>Get – Access data from one row</li><li>SCAN – Access data from a range of rows</li><li>Delete – Delete a row or a range of rows/columns.</li></ul>	<p><b>Region</b> – Another name for a <b>key range</b>. All key <b>range is contiguous</b>.</p> <p><b>Region Server</b> – Serve data for reads from or writes to a particular region/key range.</p> <p><b>Write Ahead Log (WAL)</b> – Disk commit log used for recovery.</p> <ul style="list-style-type: none"><li><b>Primary Role:</b> Durability (log on disk)</li><li>Updates appended sequentially</li></ul> <p><b>Block Cache</b> – Read cache. Uses the Least Recently Used (LRU) paradigm for block eviction.</p>	<p><b>Memstore</b> – Write cache.</p> <ul style="list-style-type: none"><li>In memory.</li><li>Sorted set of key-value pairs. Updates quickly stored since in memory.</li><li>One memstore for each column family.</li></ul> <p><b>HFile</b> – Sorted key-value pairs on disk.</p> <ul style="list-style-type: none"><li>Ideally one per column family.</li></ul> <p><b>HBase Region Flush</b> – All contents of memstore flushed to an HFile on disk.</p> <ul style="list-style-type: none"><li>Since Memstore is store, HFile is also sorted.</li></ul>	<p><b>Minor Compaction</b> – Merge multiple, small HFiles into fewer larger ones.</p> <p><b>Major Compaction</b> – Merge all HFiles into one large HFile with all records marked for deletion removed.</p>
<p><b>Data Model for Fast Writes and Reads</b></p> <ul style="list-style-type: none"><li>Layout on physical disk is predictable minimizing disk seek.</li><li>Fast access since get and put is by row key.</li><li>Since tables are sorted, scan of a key range is fast.</li></ul>	<p><b>Creation of a Key Region</b> – Table starts as a single range. <b>When a region becomes too large, it splits</b> into two child regions.</p> <p><b>Region Server</b> – Initiates a region split. The child/daughter regions are opened on the same server.</p>	<p><b>HBase Use Case #1 – High Velocity and Volume Writes.</b></p> <ul style="list-style-type: none"><li>Examples: Stock ticker, sensors, log files, system metrics. <b>Real time monitoring</b>.</li></ul> <p><b>HBase Use Case #2</b> – Information exchange with <b>high volume read and write</b>.</p> <ul style="list-style-type: none"><li>Examples: Email, chat, Facebook.</li></ul>	<p><b>HBase Use Case #3 – High volume read.</b></p> <ul style="list-style-type: none"><li>Examples: Content serving, web application back end, search index, online pre-computer view, online catalog.</li></ul>

## Lecture #13b – Recommendation

<p><b>Input to Recommender Systems</b> – Interactions between users and items.</p> <p><b>Output of Recommender Systems</b> – Suggestions of additional interactions.</p> <p><b>Common Examples:</b> Movies, music, restaurant choices, sale items at stores</p>	<p><b>Basis of Recommendation</b> – <i>Behavior of a crowd use us understand what individuals will do.</i></p> <p><b>Popular Items</b> – Co-occur with everything making them not very useful for recommendation.</p> <p><b>Anomalous Co-Occurrence</b> – Far more useful for recommendation. <b>They are the source indicators of preference.</b></p>	<p><b>History Matrix</b> – Constructed from the log files to show the history of the users for the items.</p> <ul style="list-style-type: none"> <li><b>Users by items</b></li> </ul> <p><b>Co-occurrence Matrix</b> – Quantifies how often two items appear together.</p> <ul style="list-style-type: none"> <li><b>Items by items</b></li> </ul> <p><b>Indicator Matrix</b> – Represent anomalous (i.e. interesting) co-occurrences.</p> <ul style="list-style-type: none"> <li><b>Items by items</b></li> </ul>	<p><b>Log Likelihood Ratio (LLR)</b> – Can be helpful to judge with co-occurrences can be used with confidence as indicators of preference.</p>
---	--	--	---

### Cooccurrence Analysis

### Which one is the anomalous co-occurrence?

	A	not A
B	13	1000
not B	1000	100,000

	A	not A
B	1	0
not B	0	10,000

	A	not A
B	1	0
not B	10	0

	A	not A
B	10	0
not B	0	100,000

**Bottom right is anomalous co-occurrence.**  
Consistently appear together or separate.

**User-Based Filtering** – Recommend items by finding similar users. Harder to scale.

**Item-Based Filtering** – Calculate similarity between items and make recommendations. This can be done offline.

**Dithering** – Random re-ordering of recommendation results. This makes for more off-line computation, but generally makes results better.

- Helps test relevancy of new items that would otherwise go unviewed.

- A** – Matrix of User search queries
  - Matrix is *Users* by *Queries*
- $A^T A$**  – Gives a matrix of *Queries* by *Queries*
  - Query Co-occurrence Matrix**
  - This enables query recommendation.
- B** – Matrix of User video views
  - Video View Co-occurrence Matrix**
  - Matrix is *Users* by *Videos*
- $B^T B$**  – Gives a matrix of *Videos* by *Videos*
  - This enables recommendations in the form “you may like these videos.”
- $A^T B$**  – Gives query and video view co-occurrence. **Just like a search engine.**

## Lecture #16a – Introduction to Recommendation

<p><b>Recommendation</b> – Class of machine learning that seeks to predict a user’s preference for or rating of an item.</p> <p><b>Two Main Approaches for Recommendation</b></p> <ul style="list-style-type: none"> <li><b>Collaborative Filtering</b></li> <li><b>Content-based Filtering</b></li> </ul>	<p><b>User Based Filtering</b> – Recommendation are based on similarity to other users.</p> <p><b>Item-based Filtering</b> – Recommendations are made based on similarity to other items.</p>	<p><b>Similarity Metrics</b></p> <ul style="list-style-type: none"> <li><b>Pearson Correlation</b> – Ratio of co-variance to product of standard deviations. <ul style="list-style-type: none"> <li>-1 – Inversely Proportional</li> <li>0 – No correlation</li> <li>1 – Directly proportional</li> </ul> </li> <li><b>Euclidean Distance</b> – Coordinates indicate item preference. Smaller distance means more similarity.</li> </ul>	<p><b>Tanimoto Coefficient</b> – Ratio of intersection to union. <ul style="list-style-type: none"> <li>Between 0 and 1. Bigger is more similar.</li> </ul> </p>
<p><b>Collaborative-Based Filtering</b> – <b>Deductive</b>. Needs user-item history to start to learn item associations. <ul style="list-style-type: none"> <li><b>Example:</b> last.fm</li> </ul> <p><b>Content Based Filtering</b> – <b>Inductive</b>. Relies on domain specific know to construct association between users and items. <ul style="list-style-type: none"> <li><b>Example:</b> Pandora</li> </ul> </p> </p>	<p><b>Challenges of Collaborative Filtering</b></p> <ul style="list-style-type: none"> <li><b>Cold Start</b> – No user history means no associations on day 1.</li> <li><b>Scale</b> – Huge number of products of items and users means lots of computation.</li> <li><b>Sparsity</b> – Most users express very little behavior with very few items and no behavior with the vast majority of items.</li> </ul>	<p><b>Neighborhood</b> – A group of similar users.</p> <p><b>Types of Neighborhoods:</b></p> <ul style="list-style-type: none"> <li><b>Fixed Size</b> – Cardinality (size) of the neighborhood is fixed in advance.</li> <li><b>Threshold-based</b> – Cardinality is dependent based on a threshold of similarity that is fixed in advance.</li> </ul>	<p><b>Precision</b> – Proportion of top-scoring results that are relevant.</p> <p><b>Recall</b> – Proportion of relevant results that are top-scoring.</p>
<p><b>Methods for Improving Recommender Performance</b></p> <ul style="list-style-type: none"> <li><b>Change Model Type</b> <ul style="list-style-type: none"> <li>User Based</li> <li>Item Based</li> <li>Content Based</li> </ul> </li> <li><b>Change Distance Metric</b> <ul style="list-style-type: none"> <li>Euclidean</li> <li>Tanimoto</li> <li>LogLikelihood Ratio (LLR)</li> </ul> </li> <li><b>Model Parameters</b> <ul style="list-style-type: none"> <li>K in KNN</li> </ul> </li> </ul>	<p><b>Apriori Algorithm</b> – Used to determine what people buy or use together. <ul style="list-style-type: none"> <li>Can be used for recommendation.</li> </ul> <p><b>KNN Algorithm</b> – Can be used for both classification and recommendation.</p> <p><b>Two Main Algorithms for Recommendation Engine</b></p> <ul style="list-style-type: none"> <li><b>Collaborative Filtering</b></li> <li><b>Matrix Factorization</b></li> </ul> </p>	<p><b>Fundamental Problem of Collaborative Filtering</b> – Finding a distance metric.</p> <p><b>Base Idea of Collaborative Filtering</b> – Like KNN. Make decisions based off similar things (e.g. items, users, etc.). <b>(Use collaboration from others to make recommendations)</b></p>	<p><b>ALS</b> – Inspired by matrix factorization but has almost nothing to do with it.</p> <ul style="list-style-type: none"> <li>More similar to neural networks.</li> <li>Can be random or unstable, but it works fine for some cases.</li> </ul>
